1	ADHD and Depression Attention deficit hyperactivity disorder (ADHD) is a mental health disorder that can cause above-normal levels of hyperactive and impulsive behaviours. People with ADHD may also have trouble focusing their attention on a single task or sitting still for long periods of time. If you or your child has ADHD, you're more likely to have depression as well. In fact, the rate of major depression in children with ADHD is more than five times higher than in children without ADHD. And up to 31 percent of adults with ADHD have been found to also have depression. This may feel like an unfair double whammy, but know that treatments are available for both conditions and the treatments often overlap. Talk therapy can help treat both conditions. Also, certain antidepressants, such as bupropion, can sometimes help ease ADHD symptoms. Of course, having ADHD doesn't guarantee that you'll have depression, but it's important to know it's a possibility. Find out more about the link between ADHD and depression. Tips for coping with ADHD If you or your child has ADHD, a consistent schedule with structure and regular expectations may be helpful. For adults, using lists, keeping a calendar, and setting reminders are good ways to help you get and stay organized. For children, it can be helpful to focus on writing down homework assignments and keeping everyday items, such as toys and backpacks, in assigned spots. Learning more about the disorder in general can also help you learn how to manage it. Organizations like Children and Adults with Attention Deficit Disorder or the Attention Deficit Disorder Association provide tips for management as well as the latest research. Statement : Someone who have Attention deficit hyperactivity disorder (ADHD) is able to have an above normal levels in hyperactive and impulsive behaviours. A. Yes B. No C. Not Given	Jawaban : A. Yes Pembahasan : penambahan kata baru di paragraph satu dengan kata who, able to dan in.	A
2	ADHD and Depression Attention deficit hyperactivity disorder (ADHD) is a mental health disorder that can cause above-normal levels of hyperactive and impulsive behaviours. No	Soal Tryout	Pembahasan Tryout	Jawaban
11	Supergiants can gave masses from 10 to 70 solar masses and brightness from 30,000 up to hundreds of thousands times the solar luminosity. They vary greatly in radius, ussually from 30 to 500, or even in excess of 1,000 solar radii. The Stefan-Boltzmann law dictates that the relatively cool surfaces of red supergiants radiate much less energy per unit area then those of blue supergiants; thus, for a given luminosity red supergiants are larger than their blue counterparts. The most massive superstars in the Galaxy have surface temperatures of between 20,000 – 50,000oC and appear blue in colour. They are designated ‘blue supergiants’ due to their appearance and the enormous amounts of energy that they can radiate. The best known example is Rigel, the brightest star in the constellation of Orion. It has a mass of around 20 times that of the Sun and gives out more light than 60,000 suns added together. Whereas, red supergiants are supergiant stars which are the largest stars in the universe in terms of physical size. These stars have very cool surface temperatures (3,227 – 4,227degree Celcius), and enermous radii. The four largest known red supergiants in the Galaxy are Mu Cephei, KW Sagitarii, V354 Cephei, and KY Cygni which all have radii about 1500 times that of the sun (about 7 times as far as the Earth is from the sun). The radius of most red giants is between 200 and 800 times that of the sun, which is still enough to reach from the sun to Earth and beyond. The Stefan-Boltzmann law give an order that the relatively cool surfaces of red supergiants radiate much less energy per unit area then those of blue supergiants. A. Yes B. No C. Not Given	Jawaban : A. Yes Pembahasan : Kata dictates hanya diganti dengan 1 kata kerja “give” dan 1 kata benda “order”.	A
12	Supergiants can gave masses from 10 to 70 solar masses and brightness from 30,000 up to hundreds of thousands times the solar luminosity. The most massive superstars in the Galaxy have surface temperatures of between 20,000 – 50,000oC and appear blue in colour. They are designated ‘blue supergiants’ due to their appearance and the enormous amounts of energy that they can radiate. The best known example is Rigel, the brightest star in the constellation of Orion. It has a mass of around 20 times that of the Sun and gives out more light than 60,000 suns added together. Whereas, red supergiants are supergiant stars which are the largest stars in the universe in terms of physical size. These stars have very cool surface temperatures (3,227 – 4,227degree Celcius), and enermous radii. The four largest known red supergiants in the Galaxy are Mu Cephei, KW Sagitarii, V354	Jawaban : A. Yes Pembahasan : Statement sudah sesuai dengan teks. Pola kalimat di ubah kedalam bentuk kalimat pasif.	A

	Cephei, and KY Cygni which all have radii about 1500 times that of the sun (about 7 times as far as the Earth is from the sun). The radius of most red giants is between 200 and 800 times that of the sun, which is still enough to reach from the sun to Earth and beyond. Due to their appearance and the enormous amounts of energy that they can radiate, the superstars can be designated as a “blue supergiants”. A. Yes B. No C. Not Given		
20	Supergiants can have masses from 10 to 70 solar masses and brightness from 30,000 up to hundreds of thousands times the solar luminosity. They vary greatly in radius, usually from 30 to 500, or even in excess of 1,000 solar radii. The Stefan-Boltzmann law dictates that the relatively cool surfaces of red supergiants radiate much less energy per unit area than those of blue supergiants; thus, for a given luminosity red supergiants are larger than their blue counterparts. The most massive superstars in the Galaxy have surface temperatures of between 20,000 – 50,000oC and appear blue in colour. They are designated ‘blue supergiants’ due to their appearance and the enormous amounts of energy that they can radiate. The best known example is Rigel, the brightest star in the constellation of Orion. It has a mass of around 20 times that of the Sun and gives out more light than 60,000 suns added together. Whereas, red supergiants are supergiant stars which are the largest stars in the universe in terms of physical size. These stars have very cool surface temperatures (3,227 – 4,227degree Celcius), and enormous radii. The four largest known red supergiants in the Galaxy are Mu Cephei, KW Sagittarii, V354 Cephei, and KY Cygni which all have radii about 1500 times that of the sun (about 7 times as far as the Earth is from the sun). The radius of most red giants is between 200 and 800 times that of the sun, which is still enough to reach from the sun to Earth and beyond. Red supergiants are supergiant stars which have a freezing surface temperatures. It is about 3,227 up to 4,227degree Celcius. A. Yes B. No C. Not Given	Jawaban : A. 21	Tools and hand bones excavated from the Swartkrans cave complex in South Africa suggest that a close relative of early humans known as Australopithecus robustus may have made and used primitive tools long before the species became extinct 1 million years ago. It may even have made and used primitive tools long before humanity’s direct ancestor, Homo habilis, or “handy man,” began doing so. Homo habilis and its successor, Homo erectus, coexisted with Australopithecus robustus on the plains of South Africa for more than a million years. The Swartkrans cave in South Africa has been under excavation since the 1940’s. The earliest fossil-containing layers of sedimentary rock in the cave date from about 1.9 million years ago and contain extensive remains of animals, primitive tools, and two or more species of apelike hominids. The key recent discovery involved bones from the hand of Australopithecus robustus, the first time such bones have been found. The most important feature of the Australopithecus robustus hand was the pollical distal thumb tip, the last bone in the thumb. The bone had an attachment point for a “uniquely human” muscle, the flexor pollicis longus, that had previously been found only in more recent ancestors. That muscle gave Australopithecus robustus an opposable thumb, a feature that would allow them to grip objects, including tools.	Jawaban : A. Yes Pembahasan : Statement pada soal sudah sesuai dengan teks di paragraf ke 1, kalimat ke 1.	A

	The researchers also found primitive bone and stone implements, especially digging tools, in the same layers of sediments. Australopithecus robustus were more heavily built- more “robust” in anthropological terms-than their successors. They had broad faces, heavy jaws, and massive crushing and grinding teeth that were used for eating hard fruits, seeds, and fibrous underground plant parts. They walked upright, which would have allowed them to carry and use tools. Most experts had previously believed that Homo habilis were able to supplant Australopithecus robustus because the former’s ability to use tools gave them an innate superiority. The discovery that Australopithecus robustus also used tools means that researchers will have to seek other explanations for their extinction. Perhaps their reliance on naturally occurring plants led to their downfall as the climate became drier and cooler, or perhaps Homo habilis, with their bigger brains, were simply able to make more sophisticated tools. The Swartkrans cave is a place that Tools and hand bones was excavated. A. Yes B. No C. Not Given
